How does test work? ←

- second argument does bitmask, odd end in 1, even end in 0
- I'll test odd/even
- I can use jz (jump) to see if result is even or not

↓
XOR

- set it to eax, then xor eax w/ itself
- store in result1

GDB time

gdb ./logiInst
input given gdb view commands,

(slight difference, watch(int) result1
"↓" " result2)

looks good to me!

Setup code

```
section .text  
    _start  
segment .bss  
    result1 resb 1, result2 resb 1  
section .data  
    testVar dd 5  
    zeroVar dd 20
```

Test

puts # in eax, test w/ 1
to give 1 if odd and 0 for even

↓

How do I store result?

- jz evaluates if 0, if so jumps to code block
- if not 0, cont. as normal and sets result2 to 0, jumps to exit
- If yes 0, jumps, sets result2 to 1, continues to exit

↓

Compile time!
- worked!
